4.4 Apache	11
4.5 Programming Language and Packages	11
5. Grading	12
Academic integrity: Zero tolerance on plagiarism	13

1. Overview

In this project, you will explore aspects of how streaming video works, as well as socket programming and HTTP. In particular, you will implement adaptive bitrate selection. [The programming languages and packages are specified in the development environment section.](#)

We will do this in multiple stages:

1. Preliminary stage: building a simple proxy
2. Intermediate stage: requesting and receiving video chunks (TBD)
3. Final stage: implementing adaptive bitrate streaming

1.1 In the Real World

Figure 1 depicts (at a high level) what this system looks like in the real world. Clients trying to stream a video first issue a DNS query to resolve the service's domain name to an IP address for one of the content servers operated by a content delivery network (CDN). The CDN's authoritative DNS server selects the "best" content server for each particular client based on (1) the client's IP address (from which it learns the client's geographic or network location) and (2) current load on the content servers (which the servers periodically report to the DNS server).

Once the client has the IP address for one of the content servers, it begins requesting chunks of the video the user requested. The video is encoded at multiple bitrates. As the client player receives video data, it calculates the throughput of the transfer and monitors how much video it has buffered to play, and it requests the highest bitrate the connection can support without running out of video in the playback buffer.

1.2 Your System

Implementing an entire CDN is clearly a tall order, so let's simplify things. First, your entire system will run on one host; we're providing a network simulator *netsim*

(described in [Development Environment](#)) that will allow you to run several processes with arbitrary IP addresses on one machine. Our simulator also allows you to assign arbitrary link characteristics (bandwidth and latency) to the path between each pair of “end hosts” (processes). For this project, you will do your development and testing using a virtual machine (VM) we provide.

Figure 1: In the real world...

Figure 2: Your system.

Figure 3: System overview.

Browser. You'll use an off-the-shelf web browser (e.g. Firefox) to play videos served by your CDN (via your proxy).

Proxy. Rather than modify the video player itself, you will implement adaptive bitrate selection in an HTTP proxy. The player requests chunks with standard HTTP GET requests. Your proxy will intercept these and modify them to retrieve whichever bitrate your algorithm deems appropriate. To simulate multiple clients, you will launch multiple instances of your proxy.

Web Server. Video content will be served from an off-the-shelf web server (Apache). More detail is in the [Development Environment](#) section. As with the proxy, you can run multiple instances of Apache on different fake IP addresses to simulate a CDN with several content servers. However, in the assignment, rather than using DNS redirection like a CDN would, the proxy will contact a particular server via its IP address (without a DNS lookup). A possible (ungraded) future extension to the project could include implementing a DNS server that decides which server to direct the proxy to, based on distance or network conditions from a proxy to various web servers.

The project is broken up into two stages (plus the initial set up to get you ready for the stages):

- In the [preliminary stage](#), you will implement a simple proxy that sequentially handles clients and passes messages back and forth between client and server without modifying the messages.
- In the [final stage](#), you will extend the proxy to implement the full functionality described above, with the proxy modifying HTTP requests to perform bitrate adaptation.

1.3 Groups and collaboration policy

This is an individual project, but you can discuss it at a conceptual level with other students or consult Internet material (excluding implementations of Python proxies), as long as the final code and configuration you submit is completely yours and as long as you do not share code or configuration. Before starting the project, be sure to read the [collaboration policy](#) at the end of this document.

2. Preliminary stage

Do not start until you have finished setting up your VM as described in:

☰ CSEE4119 F24 Tutorial for Setting Up Project 1 VM

You will be implementing a simple proxy that accepts client connections sequentially (i.e. handles a client, and, once it disconnects, takes care of the next client). In later stages, your proxy will be required to handle client connections concurrently.

In this preliminary stage, the proxy does NOT need to modify any messages it receives, as it will just relay the messages back and forth. In later stages, you will enhance your proxy to modify messages in order to perform adaptive bitrate selection.

2.1 Requirements

Implement a proxy that forwards messages of any length between a client and a server. See '[Get your connections right](#)' and '[Forwarding protocol](#)' for details. Note

that the VM instance is required for the final stage, but not the preliminary stage. You can work on the preliminary stage with your local devices.

2.2 Get your connections right.

Your proxy should accept connections from clients and then open up another connection with a server ([see How to run the proxy](#)). Once both connections are established, the proxy should forward messages between the client and server.

You should implement this in two steps:

a. Establish a connection with a client:

Your proxy should listen for connections from a client on any IP address on the port specified as a command line argument ([see How to run the proxy](#)). Your proxy should accept multiple connections from clients. It is not required to handle them concurrently for now. Simply handling them one by one, sequentially, will be enough.

b. Establish a connection with a server:

Once the proxy gets connected to the client, it should then connect to the server. The server IP is provided as a command line argument. As for the port number, use 8080. Make sure to close connections to the client and server when either of them disconnects.

(Figure 4) Preliminary structure

2.3 Forwarding protocol.

The “messages” that the proxy forwards follow a particular structure (for example, in HTTP, you know that there is a header and a body). This structure is important, as

the recipient of the message can know where to look to get a specific piece of information. For the preliminary stage, we keep our message structure very simple:

(Figure 5) Structure of a message

The message has a body, and an End Of Message (EOM) symbol that indicates the end of the message. In our case, we define our EOM as the new line character '\n'. Please note that detecting '\n' is different from detecting the slash character '/' and the letter 'n'.

A message has to be fully received by the proxy before being forwarded to the other side.

Here is how the forwarding protocol works in our case:

1. The proxy gets a message from the client and forwards it to the server
2. The proxy expects a response from the server, gets it, and forwards it to the client

An important thing to notice here is that there is no asynchronous forwarding (i.e., the proxy doesn't simply forward any message, it first waits for a message from the client, and then waits for a response from a server).

2.4 Running the proxy

You should create an executable Python script called **proxy** inside the proxy directory (see [below for a description of the development environment](#)), which should be invoked as follows:

```
cd ~/csee_4119_abr_project/proxy
./proxy <listen-port> <fake-ip> <server-ip>
```

listen-port: The TCP port your proxy should listen on for accepting connections from the client.

fake-ip: Your proxy should bind to this IP address for outbound connections to the server. You should not bind your proxy listen socket to this IP address— bind the listen socket to receive traffic to the specified port regardless of the IP address. (i.e. by calling `mySocket.bind(("", <listen-port>))`)

Important note: The above is a pretty unusual thing to do. You might think “In lecture, we saw that the client socket doesn’t bind, and now, you are telling us to bind the proxy’s outbound socket when connecting to the server”. However, it is necessary for the [Final Stage](#)’s [network simulator](#) to work properly, and so we will add it in this stage.

server-ip: The IP address of the server

See instructions for making your script executable in the section [Hand In](#).

2.5 Test it out!

You can test parts “[Get your connections right](#)” and “[Forwarding protocol](#)” of your proxy implementation by using the netcat tool (`nc` or `netcat`, which is installed in the [VM](#)) presented in class, using both a netcat client and a netcat server. You should be able to send a message from the client and see it appear on the server side. Then, any response sent from your server should also appear on the client. For the fake-ip, you can indicate 127.0.0.1 (localhost) when testing with netcat instances that are created on your machine.

Remember that seeing a message on the server side does not mean your implementation is 100% correct! Please be sure to come up with your own test cases and make sure that your proxy is as expected as we described in [Final Result](#).

2.6 Final result

Your proxy should be able to forward a message of any length from a client to the server, and in turn, forward the response from the server back to the client. It should support back-and-forth messages until one side closes the connection. After the

connection is closed, it should be able to accept a new connection from a client. You should be able to test the behavior of your application by creating netcat instances.

Note that this version simply forwards messages with the structure specified in Figure 2. The next stage will have a different message structure: the HTTP message structure, and you'll have to adapt your proxy based on your knowledge of HTTP messages.

2.7 What to Submit for preliminary stage

PLEASE PAY ATTENTION TO THE HANDIN STRUCTURE, AS EVEN A TYPO WILL CAUSE THE GRADER TO BREAK, WHICH CAN MAKE YOU LOSE 10 POINTS.

You will submit your project as a zipped file named **<yourUNI>.zip**. Unzipping this file should give us a directory named **handin** which should **only** contain the following:

- **proxy** — A directory named **proxy** containing **only** your source code. The code that you want to execute should be an executable named **proxy**, as described in 2.3 How to run the proxy. To make the code executable, follow these steps:
 1. Add '#!/usr/bin/env python3.10' to the top of your **proxy** Python file
 2. Run 'chmod 755 proxy' to ensure that the file has the correct permissions to be executable by us.

(Figure 6) Preliminary stage submission file structure.

You may organize your code within the **proxy** directory as you see fit. Part of your grade may be based on how understandable/organized/well-explained your code is, but we do not require any particular organization as well as it is well-organized.

2.8 Where to Submit

You will submit your code to Gradescope. If you have any questions about it, please let us know ASAP.

3. Final stage: Video Bitrate Adaptation

Details to be released later.

4. Development Environment

For the project, we are providing a virtual machine (VM) pre-configured with the software you will need. We strongly recommend that you do all development and testing in this VM; your code must run correctly on this image as we will be using it for grading. For example, some students in previous years decided to write their code on their Windows environment, which changed the control characters to **CLRF** (**Unix uses LF, thus our grader could not run their code**). Please make sure your code uses **LF**. This section describes the VM and the starter code it contains.

4.1 Virtual Machine

We provide an image on GCP (Google Cloud Platform) and you can create a virtual machine (VM) instance based on it. Please follow the [tutorial](#) to set up your VM instance and do all your testing there.

In the event you need to move files between the VM and your computer (e.g., for submission), there are a few options.

1. (recommended) Create a (private) Github repository with the relevant project files. You can push to your repository from the VM and access the files from anywhere.
2. If you SSH into your VM instance using the GCP default option (the SSH button on the same row of the instance), on the top of your SSH window, there are two arrow buttons which upload and download files.

The screenshot displays the Google Cloud Platform (GCP) VM instances interface. On the left, the 'Virtual machines' sidebar is visible, with 'VM instances' selected. The main panel shows a table of VM instances. Two instances are listed: 'abr-project-vm-1' and 'abr-project-vm-new-1'. The 'Connect' column for 'abr-project-vm-1' has an 'SSH' button highlighted with a red circle. Below the table, there are 'Related actions' such as 'Explore Actifio GO', 'View billing report', 'Monitor VMs', and 'Explore VM logs'. On the right, a 'Select an instance' panel is open, showing 'PERMISSIONS', 'LABELS', and 'MONITORING' tabs. Below the GCP interface, a browser window shows the SSH connection URL: `https://ssh.cloud.google.com/v2/ssh/projects/coms4113-sy/zones/us-central1-a/instances/abr-project-vm-1?authuser=0&hl=en...`. The browser title is 'SSH-in-browser'. The terminal window shows the Ubuntu 18.04.6 LTS login screen with system information, update notifications, and the last login time.

```

Welcome to Ubuntu 18.04.6 LTS (GNU/Linux 5.4.0-1087-rcp x86_64)

 * Documentation:  https://help.ubuntu.com
 * Management:    https://landscape.canonical.com
 * Support:       https://ubuntu.com/advantage

System information disabled due to load higher than 1.0

 * Super-optimized for small spaces - Read how we shrank the memory
   footprint of MicroK8s to make it the smallest full K8s around.

   https://ubuntu.com/blog/microk8s-memory-optimisation

2 updates can be applied immediately.
1 of these updates is a standard security update.
To see these additional updates run: apt list --upgradable

Last login: Thu Sep 22 21:06:24 2022 from 35.235.244.33
sy3011@abr-project-vm-1:~$

```

3. Launch your remote desktop. You can use sidebar options to upload and download files. Alternatively, send the files via the Internet (email, Google Drive). Firefox is installed on the VM.

4.2 Starter Files (*for final stage*)

Details to be released later.

4.3 Network Simulation (*for final stage*)

Details to be released later.

4.4 Apache

Details to be released later.

4.5 Programming Language and Packages

This project must be implemented in **Python 3**. Your VM instance comes with Python version 3.10.12, which is the version we will use to test your code. If this choice of language poses a significant problem for you (i.e., you have never used Python before), please contact the instructors.

To run python 3.10.12 on the VM instance, please use the following command:

python3

To install python packages for version 3.10.12 on the VM instance, please use:

python3 -m pip

For this project, you are allowed to use the following python packages:

sys, socket, threading, select, time, re, numpy, subprocess

Using an unallowed package in your code may result in no credit being given. Other than the packages listed, you may only use the package if you ask on Ed Discussion **and** a TA or the professor explicitly responds to your request approving the use. We will maintain a pinned Ed post titled "Project 1 List of Approved (and Disallowed) Packages", so please check that post before posting your request. If you would like to use a package not mentioned here and are unsure if it would be acceptable, please **add a new followup discussion** under the above mentioned pinned post on Ed at least 3 days in advance of the project deadline.

In your followup discussion, you must mention the package name, the package version, and a link to the official repository of the package (e.g. <http://pypi.python.org/pypi>). TAs will examine your request and determine if the package is allowed and add it to the list of allowed/disallowed packages.

5. Grading

Your grade will consist of the following components:

Proxy (70 points)

- Preliminary stage proxying [15 pts]
- Final stage proxying runs on browser [10 pts]
- Final stage proxy - implementing EWMA throughput estimator & bitrate adaptation [35 pts]
- DNS Server - correct responses and implementation of web server selection [10 pts]
- Code executes as instructed [-10 pts if we have to manually debug things]

Writeup (20 points)

- Plots of utilization, fairness, and smoothness for $\alpha \in \{0.1, 0.5, 0.9\}$ [10 pts]
- Discussion of tradeoffs for varying α [10 pts]

Style (10 points)

- Code thoroughly commented
- Code organized and modular
- README listing your files and what they contain

Please make sure your code runs as an executable and as described in Running the Proxy ([Preliminary Stage](#), [Final Stage](#)) before submitting. Code that does not run may receive a zero on the assignment.

We **WILL NOT** release our grading scripts, nor specifically tell you what we will test for. Be sure to stress test your code in a variety of scenarios using unexpected inputs. Be sure to **PRECISELY** follow the instructions in this document for proxy development: implement exactly what is asked of you, no more and no less. For example, do not implement command line argument validation, we didn't ask you to.

Academic integrity: Zero tolerance on plagiarism

The rules for [Columbia University](#), the [CS Department](#), and the EE Department (via SEAS: [1](#) and [2](#)) apply. It is your responsibility to carefully read these policies and ask the professor (via Ed) if you have any questions about academic integrity. Please ask the professor before submitting the assignment, with enough time to resolve the issue before the deadline. A misunderstanding of university or class policies is not an excuse for violating a policy.

This class requires closely obeying the policy on academic integrity, and has zero tolerance on plagiarism for all assignments, including both projects/programming assignments and written assignments. By zero tolerance, we mean that the minimum punishment for plagiarism/cheating is a 0 for the assignment, and all cases will be referred to the Dean of Students.

This assignment must be completed individually. For programming assignments, in particular, you must write all the code you hand in yourself, except for code that we give you as part of the assignments. You are not allowed to look at anyone else's solution (including solutions on the Internet, if there are any), and you are not allowed to look at code from previous years or ask people who took the class in previous years for help. You may discuss the assignments with other students at the conceptual level, but you may not write pseudocode together, or look at or copy each other's code. Helping other students violate the policy (for example, letting them look at your code) is a violation, even if you completed the code yourself. Please do not publish your code or make it available to future students -- for example, please do not make your code visible on Github. Uploading course materials to sites such as CourseHero, Chegg or Github is academic misconduct at Columbia (see [pg 10](#)).

You may look at documentation from the tools' websites. However, you may not use external libraries or any online code unless granted explicit permission by the professor or TA. For written (non-programming) answers, if you quote material from textbooks, journal articles, manuals, etc., you **must** include a citation that gives proper credit to the source to avoid suspicion of plagiarism. If you are unsure how to properly cite, you can use the web to find references on scientific citations, or ask fellow students and TAs on Ed.

You are not allowed to use GitHub Copilot, Kite, or similar tools. **Using AI-assisted coding tools (such as GitHub Copilot) is considered academic dishonesty.**

Since "AI-assisted" can be somewhat vague, I will clarify that "AI-assisted tools" includes, but is not limited to, any coding tools that require access to the internet or more than 2MB of data for semantic analysis (we are setting the size bar rather high because the GCC executable is inexplicably large; the intention is that you should not be performing analyses using a sizable dataset).

For each programming assignment, **we will use software to check for plagiarized code.**

Note: You *must* set permissions on any homework assignments so that they are readable only by you. You may get reprimanded for facilitating cheating if you do not follow this rule.
